

Crude, but helpful, typesetting script from meXml

In my quest to create a set of free and open tools for platinum, scholar-run OA journals, I've [just committed](#) a crude, provisional script to my [meXml git repository](#) that assists with typesetting into pseudo-NLM format.

A few notes. First of all, what does it do? The script parses markup output from the [wysihtml5 tool](#) and converts it into near-as-damnit the format I need for typesetting. The idea is that I paste a LibreOffice document (with endnotes, not footnotes) into the tool, and grab the markup it returns. This python script then parses it one step further into the format that I need to generate galleys for Orbit with the [/tools/gengalleys.sh](#) tool. I still have to clean up the markup, but this has reduced the time it takes to typeset down from about 6-8 hours to about 2 hours.

Is this the best way to do it? Almost certainly not. Why? Because the way to do it properly would be to create a set of LibreOffice styles (or whatever mechanism it uses) and then get their tool to directly output in the format that's needed. It's also the case that I have broken compatibility with NLM standards (at present) in my implementation. This is something that I aim to gradually fix; I needed to break it at the time to Just Get It Done (trademark).

Is the script complete? Nope. It's pretty sloppy coding, too. Again, this is a dirty hack that I've committed in case it helps somebody.

Disclaimers done: enjoy!
