

Step 1 is to put the following in a file called cli.ini inside your Let'sEncrypt directory:

```
# This is an example of the kind of things you can do in a configuration file.
# All flags used by the client can be configured here. Run Let's Encrypt with
# "--help" to learn more about the available options.

# Use a 4096 bit RSA key instead of 2048
rsa-key-size = 4096

server = https://acme-v01.api.letsencrypt.org/directory

# Uncomment and update to register with the specified e-mail address
email = your@email.com

# Uncomment and update to generate certificates for the specified
# domains.
domains = www.domain.com, domain.com

# Uncomment to use a text interface instead of ncurses
text = True

# Uncomment to use the standalone authenticator on port 443
authenticator = apache
```

You should change the “domains” and “email” line, as appropriate, for your site.

Step 2 is to run the following command:

```
./letsencrypt-auto --renew -c cli.ini certonly
```

If this works then you won't be prompted to enter any information by hand and the process will silently complete. Then check your live site and see if the certificate has been renewed. If it has, then you can add this line to your Crontab to run every 30 days (once per month).
